Regression (Day 13: wins ~ goal_difference)

MAE = 1.37, MSE = 3.53, RMSE = 1.88 wins, R^2 = 0.879. Predictions are typically off by about 1.88 wins, versus 5.40 wins for a mean-only baseline. 5-fold CV RMSE = 1.94 ± 0.10, so the score is stable. Most important metrics: RMSE and MAE, because they measure prediction errors directly in wins. Trust: fairly good. Goal difference tracks wins closely, but it is a single feature, and 42-game seasons are mixed with 38-game ones.

Classification (Day 14: relegation prediction)

LogReg: accuracy = 0.978, precision = 1.00, recall = 0.857, F1 = 0.923. Tree: accuracy = 0.942, precision = 0.842, recall = 0.762, F1 = 0.800. Confusion matrix: LogReg missed 3 relegated teams (FN) and falsely flagged 0 (FP). 5-fold CV F1 = 0.840 ± 0.041 for LogReg and 0.816 ± 0.077 for the Tree. Most important metrics: recall and F1. Missing a relegated side is the costly error, and accuracy can be misleading because around 85% of teams stayed up. Trust: moderate. Logistic Regression clearly beats the baseline and is relatively stable across folds, but there are only 21 relegated teams in the test set, so performance estimates may vary with different data.
